

Wishlisted demand stalls on doubt, not price — so we resolve doubt, in the app.

Lifting 30-day wishlist-to-purchase for Myntra — without a single rupee of discount.

HOW THE THINKING EVOLVED

Live artefacts: [Discovery Engine](#) · [MVP prototype](#) · [Research kit](#)

BUSINESS METRIC DECOMPOSITION

Confidence is the only high-frequency lever we can pull without discounts

$$W2P (30\text{-day}) = \text{Reach} \times \text{Recall} \times \text{Confidence} \times \text{Intent} \times \text{Checkout}$$

The insight: Price stalls the most saves — but it's **out of scope** under the no-money constraint, and checkout friction isn't wishlist-specific. That leaves **Confidence** as the highest-frequency lever we can actually pull.

Wishlist = purchase intent already captured. We monetise demand that's already here — no acquisition, no discount.

An AI-designed engine turns thousands of reviews into a ranked opportunity map

Goes beyond sentiment: it quantifies and ranks competing opportunities against the business metric — and enforces the constraint by design.

▶ [Try the engine live](#)

Fit, quality & styling doubt — not price — is the biggest solvable blocker

Theme frequency across the sample corpus of public-review snippets (illustrative; recomputes live on any real dataset)

Why confidence wins

~1 in 2

stalls mention a fit / quality / styling doubt — every one solvable in-app.

Price ranks #2 on raw frequency — but it's the one lever the constraint forbids. Noise for us, not signal.

Source: public reviews (Trustpilot, PissedConsumer, Quora, Play / App Store, Reddit themes), tagged by the Discovery Engine.

6 interviews confirm which doubt dominates — and for whom

The design

- **Segment** High-intent wishlist staller: 10+ saved items, saved-not-bought in 30 days, monthly Myntra users.
- **Core technique** A live wishlist walk-through — respondents screen-share and narrate 3–4 saved-but-unbought items.
- **We separate** Confidence-blocked vs price-blocked users, tagging the dominant doubt per item.
- **Anti-bias** Ask about the last real instance, never pitch a solution, probe 3× why.

What we're filling in (from real interviews)

Dominant-doubt tally across all walked-through items

— Fit	— Quality	— Styling	— Price	— Other
------------------	----------------------	----------------------	--------------------	--------------------

Representative verbatim quotes (to insert)

“ _____ ”

“ _____ ”

Hypothesis to test: fit dominates for apparel / occasion buyers; quality for value-seekers. Research decides the final problem.

PROBLEM DEFINITION

Saved items go cold because the app can't answer “will it fit, is it good, will it suit me”

● Target segment

High-intent wishlist stallerers — save 10+ items, mean to buy several, but repeatedly defer. Skew women's apparel & occasion wear; not bargain-only browsers.

● Product outcome

↑ share of saved items whose blocking doubt is resolved in-app
→ ↑ wishlist→purchase in 30 days, with no price change.

● Root cause

After “I like this,” the PDP can't answer fit, quality or styling — the three questions that gate the buy — so the user leaves to find certainty.

● Existing workarounds

Google / YouTube reviews · ask friends on WhatsApp · order 2–3 sizes to return the misfits · check other apps · or just “wait.”

Why it matters: we convert demand already captured (margin-safe, no discount) and better-matched buys should **lower returns** — a second P&L win.

Resolve the doubt at the moment of hesitation — no coupon, margin-safe

Today: users leak out of the app

- ↗ Open Google / YouTube for real-wear reviews
- ↗ Screenshot to friends on WhatsApp for a verdict
- ↗ Order multiple sizes, plan to return misfits
- ↗ Re-check the item on a competitor app
- ↗ Give up — item goes cold in a 40-item pile

Instead: certainty, in-app, in seconds

- **Fit** — a fit-finder predicts your size from a brand you own
- **Quality** — a synthesised buyer verdict, not a star average
- **Styling** — where it works + how real buyers styled it
- **Decision** — a confidence read that tips “saved” into “bought”
- **No money** — zero discount — pure confidence, margin safe

Strategic fit: attacks the exact leak point · complies with the no-money constraint · likely reduces returns · re-uses demand we already paid to acquire.

The Wishlist Confidence Assistant clears fit, quality & styling in three taps

A working prototype, not a mockup

- 1 Fit-finder that actually computes**
Enter a brand & size you own; it returns your size for this item from real per-brand sizing bias, plus a fit-risk read.
- 2 Buyer verdict, not a star average**
Structured tags from real reviews & photos — “fabric matches 88%”, “runs small — size up”.
- 3 Styling & occasion match**
Confirms where it works and how other buyers styled it — the “will it suit me” answer.
- 4 A meter that tips the decision**
Each resolved doubt lifts the score; at ~92% “Add to Bag” unlocks — no discount in the flow.

DEFINING SUCCESS

We win only if assisted wishlist→purchase rises while returns stay flat

NORTH STAR **Assisted W2P (30-day)** — 30-day wishlist→purchase among assistant users vs. a holdout.

LEADING INDICATORS

Uncertainty-resolution rate

% of sessions resolving ≥ 1 of fit / quality / styling

Confidence-to-cart

% of resolved items added to bag in 24h

Assistant adoption

% of wishlist views that open it

GUARDRAILS (must not worsen)

Return rate on assisted orders

confidence without correctness = a false win

Notification opt-out / uninstall

resurfacing must not annoy

AOV & net margin

conversion lifted with no price giveaway

COUNTER-METRIC

Vanity wishlist adds

optimise high-intent conversion, not raw saves

Time-to-decision

should shrink, not become a research chore

Ship gate & test: adoption $\geq 15\%$ of item-views and resolution $\geq 40\%$ of sessions to ship; success = assisted W2P up vs holdout with flat-or-lower returns over a 4-week A/B.

RISKS & MITIGATION

The biggest risk is confidence without correctness — so returns is a hard guardrail

● Confidence ≠ correctness

We lift conversion but inflate returns.

Mitigate: Return rate is a hard guardrail; calibrate the fit model on realised return data; A/B auto-halts if assisted returns rise.

● Cold-start items

Long-tail SKUs lack the reviews the verdict needs.

Mitigate: Graceful degradation — fit-finder works from size logic alone; label low-data items; use the gap to seed structured reviews.

● Maybe it really is price

If most stalls are price, a confidence tool moves a minority.

Mitigate: Interviews size price- vs confidence-blocked users; target confidence first; price handled only via non-monetary levers.

● Adoption / trust

Users ignore a new surface, or distrust an AI verdict.

Mitigate: Trigger at the hesitation moment; first answer useful in 2 taps; ground every claim in cited real-buyer data, never invented.

Metric → Confidence lever → AI discovery ranks fit / quality / styling → interviews confirm → Assistant resolves doubt in-app → assisted W2P up, returns flat, no discount.
